Introduction: We investigated the anticancer effect and systemic effect of the atellocollagen (AC) patch coated nucleoline-aptamer-conjugated Gemcitabine (IO401 patch) by directly implanting to the tumor cell in pancreatic cancer patient-derived xenograft (PDX) model to purpose a future potent adjuvant surgical strategy during curative pancreatic resection for pancreatic cancer.

Methods: Pancreatic cancer PDX model was established. Animals were grouped randomly (7 mice per group) into three types of patch transplantation groups: G1= Null AC patch, G2= Gemcitabine AC patch, G3= IO401 patch. Tumor volume (length x width², mm³), Tumor weight (mg), and Tumor inhibition rate \[ 1 - (T_i - T_0) \] / (average tumor volume of group) x 100, Ti=endpoint tumor volume, T₀=start tumor volume] were calculated. Anticancer therapy-related toxicity was evaluated by hematologic and histological findings.

Results: G3 (IO401 patch) showed the most significant reduction of tumor growth and tumor weight comparing with G1 (Null AC patch) and G2 (Gemcitabine AC patch) (p =0.014, p=0.018). G3 also showed the most significant tumor inhibition rate comparing with G1 and G2 (p =0.011). G2 and G3 has the low necrosis proportion in histological finding comparing with G1 (p =0.005, p<0.05). Moreover, no leukopenia, no anemia, and no neutropenia were observed in G3.

Conclusions: We demonstrated the anticancer effect of the IO401 patch by directly implanting to tumor cell in pancreatic cancer PDX model. This directly implantable aptamer-drug conjugate system on tumor cell is expected to be a new surgical strategy to further increase the oncological importance of margin negative resection in pancreatic cancer surgery. Further research will be needed.
